ROCK FALL EXPLANATIONS (20+)

- A large number of explanations were put forward by the parties involved, many of them with ulterior motives: unsuitable section, inappropriate and damaging explosive, poor workmanship (drilling, bolting, etc.), untested rock bolts, too differed bolt grouting, poor site organisation, unsuitable numerical and structural models, underdesigned rockbolts, inappropriate bolting patterns, unsuitable excavation sequence, poor and inefficient quality control, lack of design methodology (EC7), lack of monitoring and inspection, unforeseen stress release, random vertical joints, lack of spot bolt decision on visible instabilities, inclined defects in sheet facies, too high water pressure imposed in the fissures, etc.
- At that stage, none of the specified monitoring measures that had been prepared for design validation (geological joint mapping, convergence measurement, profile mapping, pull-out test, etc.), that certainly would have helped as new design basic data, had been implemented.
- Maintaining roof integrity was crucial for stability, as was established latter (You et al. Johannesburg ISRM2003)

Géotechnique des ouvrages souterrains

comportements post rupture

PREMIÈRES CONCLUSIONS

- Le concept est encore un objet de recherche
- La définition des modes de rupture n'est pas toujours aisée
- Le phénomène peut aussi être relatif.
